

SALESTORM SYSTEM DESIGN HACKATHON

High-Scale E-Commerce Flash-Sale Architecture Blueprint
Complete Systems Design, Visual Diagrams & Concurrency Models

Team Radeons | SYSCRAFTERS 2026 Architecture Challenge

Core Scale Benchmark: 10,000 Concurrent HTTP Requests Competing for Exactly 100 Available Inventory Units.

Architectural Guarantees: Zero Overselling (100% Invariant) • Idempotent Financial Settlement • 30s Outage Recovery Saga

Engineering Target: P99 Response Latency < 250 ms • 100% Memory Fast-Rejection of Exhausted Traffic

01. Requirements & Assumptions Document

Project: SALESTORM Flash-Sale Platform

Target Event: Limited-Stock High-Scale Flash Sale

Core Scale Target: 10,000 concurrent purchase requests for 100 available units of Product X

Author: System Architecture & Engineering Consulting Unit

1. Executive Summary & Business Context

SALESTORM is preparing for a high-demand flash sale campaign where customer demand exceeds available inventory by two orders of magnitude (10,000 concurrent shoppers competing for 100 units of physical stock). During such flash-sale spikes, traditional e-commerce architectures face critical failure modes:

- 1. Inventory Overselling:** Race conditions at the database layer allowing more than 100 successful checkouts, resulting in canceled orders, customer dissatisfaction, and regulatory penalties.
- 2. Database Contention Collapse:** Thousands of concurrent connection threads contending for a single database row, exhausting connection pools (HikariCP) and causing cascading gateway timeouts.
- 3. Double Charging & Lost Transactions:** Unhandled payment retries and downstream service outages (e.g., Order Service downtime) leading to duplicate charges or paid orders vanishing.

This document establishes the formal functional boundaries, strict guarantees versus engineering targets, and operational constraints governing the SALESTORM platform.

2. The Required Business Pipeline

The platform must support the complete end-to-end customer journey:

\$Customer → Product Discovery → Cart → Inventory Check → Inventory Reservation → Checkout → Payment → Order → Fulfilment → Shipment → Notification → Delivery Tracking\$

3. Functional Requirements

3.1 Product Discovery & Inventory Display

- **FR-01:** Real-time catalog display showing flash sale product specifications, pricing, countdown timer, and inventory availability status.
- **FR-02:** When available units reach zero, the user interface and API must immediately transition to "Sold Out", rejecting further checkout attempts.

3.2 Inventory Reservation

- **FR-03:** Customers clicking "Buy Now" must initiate an atomic inventory reservation request.
- **FR-04:** Maximum reservation limit of **1 unit per authenticated customer** per flash sale event.
- **FR-05:** Upon successful reservation, a unique `reservation_id` is issued, and the unit is held for a **10-minute hold window** (600 seconds).

- **FR-06:** If payment is not completed within 600 seconds, the hold expires automatically, and the reserved unit returns to the available inventory pool.

3.3 Checkout & Payment Processing

- **FR-07:** The customer must submit payment authorization referencing a valid, unexpired `reservation_id`.
- **FR-08:** Payment processing must support idempotency using a client-supplied X-Idempotency-Key to prevent duplicate charges upon network retries or double clicks.
- **FR-09:** On payment success, the payment record transitions to `SUCCESS`, and the reservation transitions to `CONFIRMED`.
- **FR-10:** On payment failure (e.g., insufficient funds, card declined), the reservation is immediately released (`RELEASED`), and the item is returned to the available stock pool.

3.4 Order Settlement & Fulfillment

- **FR-11:** Confirmed payments must trigger guaranteed asynchronous order creation.
- **FR-12:** If the Order Service experiences a temporary outage, payment success events must be durably preserved and processed upon service recovery.
- **FR-13:** Asynchronous dispatch of order confirmation notifications (Email/SMS) and handoff to 3PL logistics for shipment tracking.

4. Non-Functional Requirements: Strict Guarantees vs. Engineering Targets

The architecture distinguishes between non-negotiable **Strict Guarantees** (which must never be violated under any failure condition) and **Engineering Targets** (which guide performance and capacity planning).

Category	Requirement	Specification	Classification	Enforcement Mechanism
Consistency	Zero Overselling	Total Confirmed Sales ≤ 100 . Never allow <code>available_quantity < 0</code> .	Strict Guarantee	Redis Lua Atomic Pre-allocation + MySQL InnoDB row CHECK constraints
Integrity	Payment Idempotency	Exactly-once payment capture. 0 duplicate financial charges.	Strict Guarantee	Distributed Redis lock + MySQL <code>idempotency_key</code> unique index
Reliability	Zero Data Loss	No paid orders lost during 30s downstream service outage.	Strict Guarantee	Transactional Outbox Pattern + Apache Kafka persistent log
Lifecycle	Automated Stock Reclaim	Expired or failed reservations released within $600s \pm 5s$.	Strict Guarantee	Redis TTL eviction + Background Scheduled MySQL Reaper Job
Performance	Reservation Latency	$P95 < 100\text{ ms}$, $P99 < 250\text{ ms}$ under 10k concurrent requests.	Engineering Target	In-memory atomic Lua scripts with fast-fail HTTP 409 rejections
Throughput	Burst Concurrency	Handle 10,000 concurrent checkout attempts at <code>t_0</code> .	Engineering Target	Asynchronous decoupling, reactive gateway, and horizontal pod

				autoscaling
Throughput	Read Scalability	Support 500,000 req/s catalog read queries.	Engineering Target	Edge CDN caching (Cloudflare) + Redis distributed cache-aside
Availability	Platform Uptime	99.99% availability for browsing, discovery, and cart.	Engineering Target	Multi-AZ deployment, load balancing, circuit breakers
Disaster Recovery	Recovery Objectives	RPO = 0 (zero transactional data loss), RTO < 30 s.	Engineering Target	Kafka multi-broker replication and MySQL semi-synchronous replication

5. Assumptions & Constraints

1. **Flash Sale Inventory Allocation:** Exactly 100 units of Product X are pre-allocated for the flash sale event.
2. **Traffic Surge Profile:** 10,000 authenticated users click "Buy Now" within a 5-second window. Inbound duplicate request rate is estimated at 2% due to rapid double clicks or mobile network retries.
3. **Payment Provider Behavior:** External payment gateway (Stripe/PayPal) exhibits a 95% success rate, 5% failure rate, and an average response latency of 800 ms with occasional transient timeouts.
4. **Hardware & Infrastructure Limits:** Relational database connection pool is limited to 50 active connections per instance (HikariCP). The database must be shielded from direct 10,000-thread concurrent row contention.
5. **Downstream Resiliency Test Case:** The system must gracefully tolerate an unexpected 30-second complete outage of the Order Service without dropping customer orders or creating data anomalies.

02. High-Level Architecture (HLD)

Project: SALESTORM Flash-Sale Platform

Phase: Stage 2 — Architecture & High-Level Design

Author: Principal System Architect

1. System Context Diagram (C4 Level 1)

The System Context diagram describes SALESTORM's position within the enterprise ecosystem, its user personas, and its external third-party dependencies.

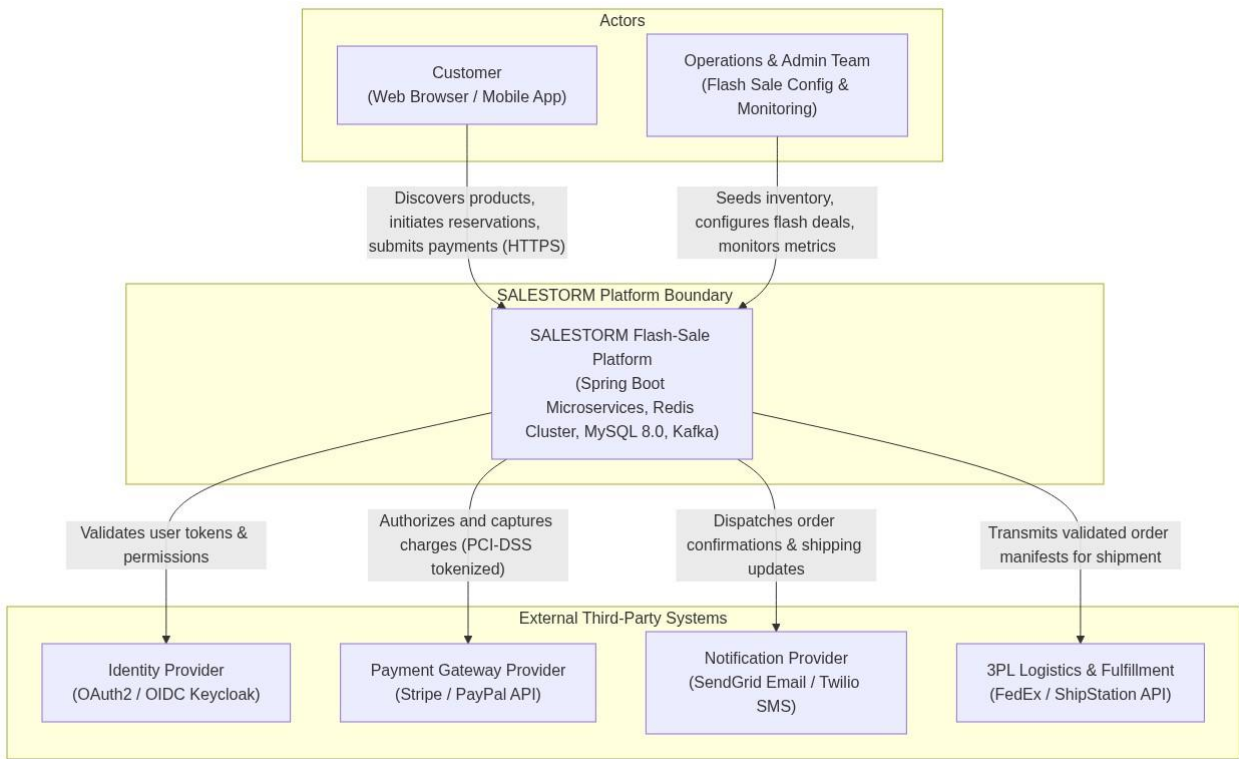

Figure 1: System Context Diagram (C4 Level 1) - Actors & Platform Boundary

2. Container & Service Architecture Diagram (C4 Level 2)

The container diagram illustrates the microservice decomposition, data persistence boundaries, caching layers, and asynchronous messaging topologies.

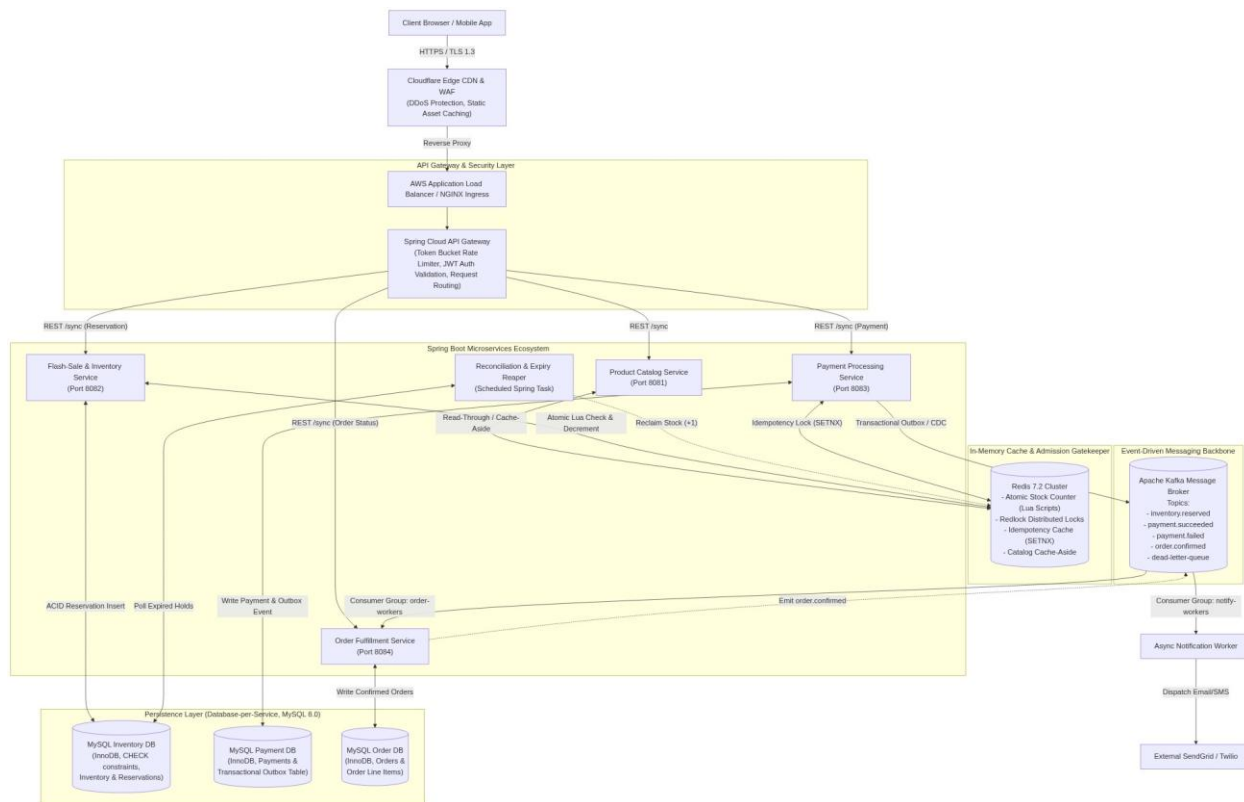

Figure 2: Container & Service Architecture Diagram (C4 Level 2) - Core Topology

3. Component Justifications & Bottleneck Analysis

Component	Primary Architectural Purpose	Potential Bottleneck Under 10k Concurrency	Mitigation Strategy
Cloudflare CDN & Edge WAF	Absorbs static catalog traffic, blocks malicious scrapers, terminates TLS at edge.	Edge cache misses during price updates.	High TTL for static catalog data with instant webhook-based purge on price/stock mutation.
Spring Cloud API Gateway	Centralized ingress routing, JWT token extraction, and token-bucket rate limiting.	Netty event loop thread saturation under request surges.	Horizontal Autoscaling (HPA), non-blocking reactive filters, short request timeout limits (2s).
Redis 7.2 Cluster	Primary Traffic Gatekeeper: Executes atomic Lua check-and-decrement in < 0.3 ms, filtering 99% of requests in memory.	Single Redis shard CPU saturation or network I/O limits.	Single-key Lua script benchmarked at > 120,000 ops/sec. Cluster sharding with read replicas for status reads.
Flash-Sale Inventory Service	Validates customer limits and persists reservation holds into MySQL.	HikariCP database connection pool exhaustion if 10k threads hit MySQL simultaneously.	Two-Tier Architecture: Only the 100 requests granted by Redis ever enter MySQL; remaining 9,900 are fast-rejected.
Payment Service	Idempotently coordinates	External Stripe latency	Non-blocking HTTP client

	with third-party payment gateways; uses Transactional Outbox.	(800ms) causing thread blocking.	(WebClient), Resilience4j circuit breaker, and async event dispatch.
Apache Kafka Broker	Buffers high-volume events, decouples Payment from Order Service, prevents data loss during outages.	Consumer lag during downstream crashes or partition hot-spotting.	Partitioning by customer_id, durable SSD log segments, consumer auto-recovery upon restart.
MySQL 8.0 Primary-Replica	Systems of record for financial auditability, ACID transactions, and hardware CHECK constraints.	Lock contention and disk I/O on single product row.	Row-level locking scoped strictly to 100 transactions; read replicas offload all reporting traffic.

4. Communication Protocols: Synchronous vs. Asynchronous Matrix

Service Boundary	Protocol	Pattern	Justification
Client → API Gateway	HTTPS / TLS 1.3	Synchronous REST	Client requires immediate synchronous feedback (reservation token or out-of-stock notification).
Gateway → Inventory Service	HTTP/2 REST	Synchronous Request-Response	Strict hold guarantee: Client must immediately obtain reservation_id or 409 Conflict.
Inventory → Redis	RESP3 TCP	Synchronous Atomic Lua	Redis executes in < 1 ms; atomic serial execution guarantees zero overselling.
Inventory → MySQL	JDBC (HikariCP)	Synchronous ACID Transaction	Guarantees durable persistent reservation before client proceeds to payment.
Payment → External Gateway	HTTPS REST	Synchronous with Circuit Breaker	Financial authorization requires authoritative external confirmation.
Payment → Order Service	Apache Kafka	Asynchronous Event-Driven Saga	Decouples services: If Order Service is down for 30s, Payment completes without error; Order consumes event on recovery.
Order → Notification	Apache Kafka	Asynchronous Publish-Subscribe	Customer notification must not block the core checkout execution critical path.

5. Docker-Based Deployment Architecture

The following deployment topology isolates internal networks, configures multi-replica services, and provides durable volume mounts.

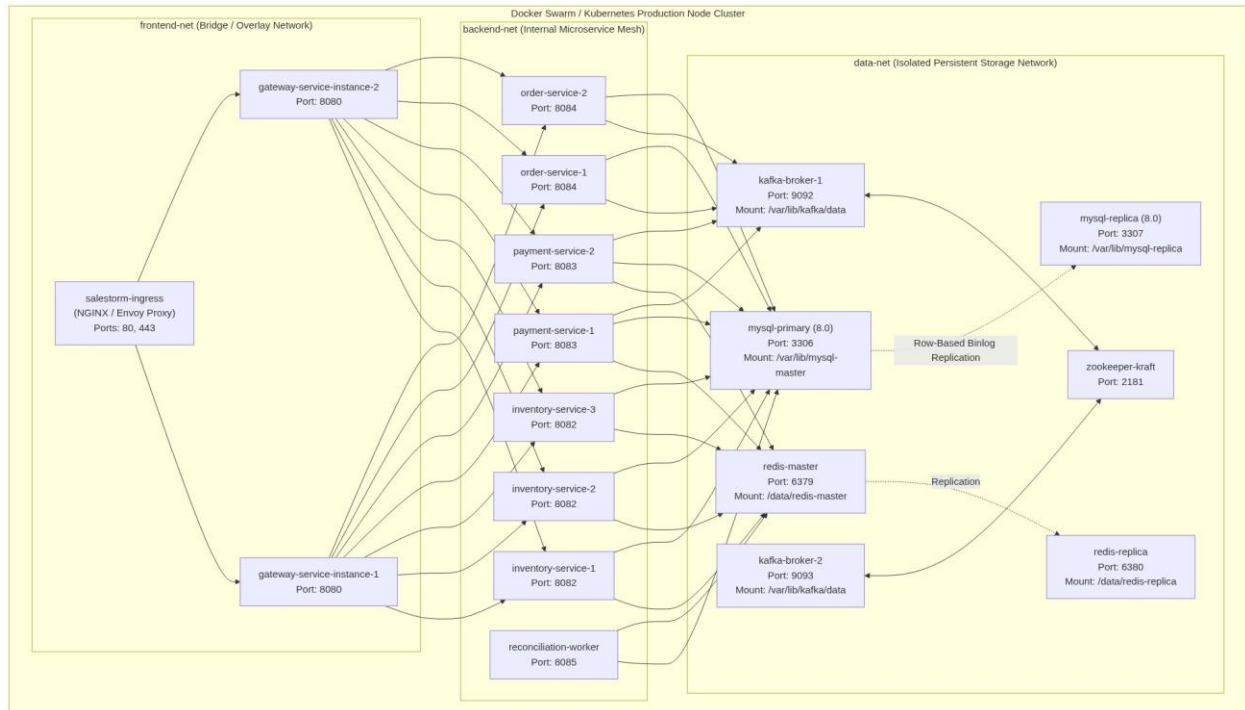

Figure 3: Docker-Based Deployment Architecture - Multi-Tier Isolated Networks

6. Scaling to 50× Traffic Surge (500,000 req/s)

If inbound traffic surges by 50× (from 10,000 to 500,000 requests per second):

- Edge Offloading:** Cloudflare CDN serves cached static catalog pages and countdown timers directly from edge Points of Presence (PoPs), absorbing 95% of read traffic.
- Gateway Tier Auto-Scaling:** Spring Cloud Gateway horizontally scales from 2 to 20 instances via Kubernetes Horizontal Pod Autoscaler (HPA) targeting 70% CPU utilization.
- Redis Cluster Partitioning:** Redis stock keys are pre-sharded across multiple hash slots. Single-threaded Lua script throughput scales linearly across cluster nodes.
- Fast-Drop Gate:** The moment Redis stock reaches 0, the API Gateway immediately enables an in-memory circuit breaker flag (`LOCAL_STOCK_DEPLETED = true`), returning HTTP 409 responses at the gateway layer without generating any downstream network hops.

03. Low-Level Design (LLD)

Project: SALESTORM Flash-Sale Platform

Phase: Stage 5 — Low-Level Object-Oriented Design

Author: Principal System Architect

1. Domain Class Diagram (Inventory, Payment, and Order Modules)

The low-level design structures the system into decoupled domain aggregates, repositories, and polymorphic strategy providers.

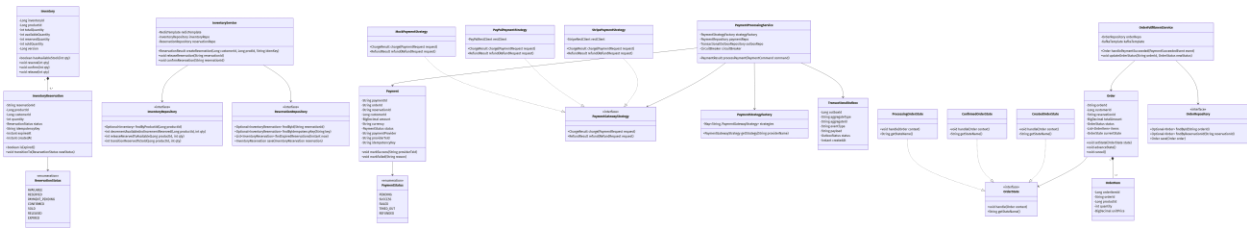

Figure 4: Domain Class Diagram - Inventory, Payment, and Order Modules

2. Module Responsibilities & Domain Invariants

2.1 Inventory Domain

- **Aggregate Root:** Inventory represents the authoritative physical quantity of a SKU.
- **Invariant 1:** $\text{available_quantity} + \text{reserved_quantity} + \text{sold_quantity} = \text{total_quantity}$ at all times.
- **Invariant 2:** $\text{available_quantity} \geq 0$ (enforced by code and MySQL hardware CHECK constraint).
- **Invariant 3:** Exactly one active reservation exists per customer for a given flash-sale product.

2.2 Payment Domain

- **Aggregate Root:** Payment models the financial authorization transaction.
- **Invariant 1:** A payment cannot be captured without an active, unexpired `reservation_id`.
- **Invariant 2:** Exact-Once processing is enforced by validating `idempotency_key`. A duplicate payment request never initiates a second charge to an external payment processor.
- **Invariant 3:** The payment record and its corresponding `TransactionalOutbox` domain event are committed inside the exact same local ACID transaction.

2.3 Order Domain

- **Aggregate Root:** Order represents the legal customer purchase contract.
- **Invariant 1:** An order cannot transition to `CONFIRMED` unless backed by a verified `payment_id` and valid `reservation_id`.
- **Invariant 2:** Order creation is strictly idempotent: re-delivering a `PaymentSucceededEvent` from Kafka produces the existing order rather than creating duplicate orders.

3. Error Handling and Validation Architecture

6. **Fast-Fail Layer (JSR-380 / Bean Validation):** Incoming DTOs are validated at controller boundary (`@NotNull`, `@Positive`, `@Pattern(regexp = "[0-9a-fA-F-]{36}$")`).
7. **Business Exception Hierarchy:**

- OutOfStockException → Mapped to HTTP 409 Conflict.

- DuplicateRequestException → Mapped to HTTP 409 Conflict or replay cached response.

- PaymentFailedException → Mapped to HTTP 402 Payment Required.

- ReservationExpiredException → Mapped to HTTP 410 Gone.

8. **Global Controller Advice:** Returns standard **RFC 7807 Problem Details** for HTTP APIs.

04. Database & Concurrency Design

Project: SALESTORM Flash-Sale Platform

Phase: Stage 3 — Concurrency & Database Architecture

Author: Principal System Architect

1. Entity-Relationship Diagram (ERD)

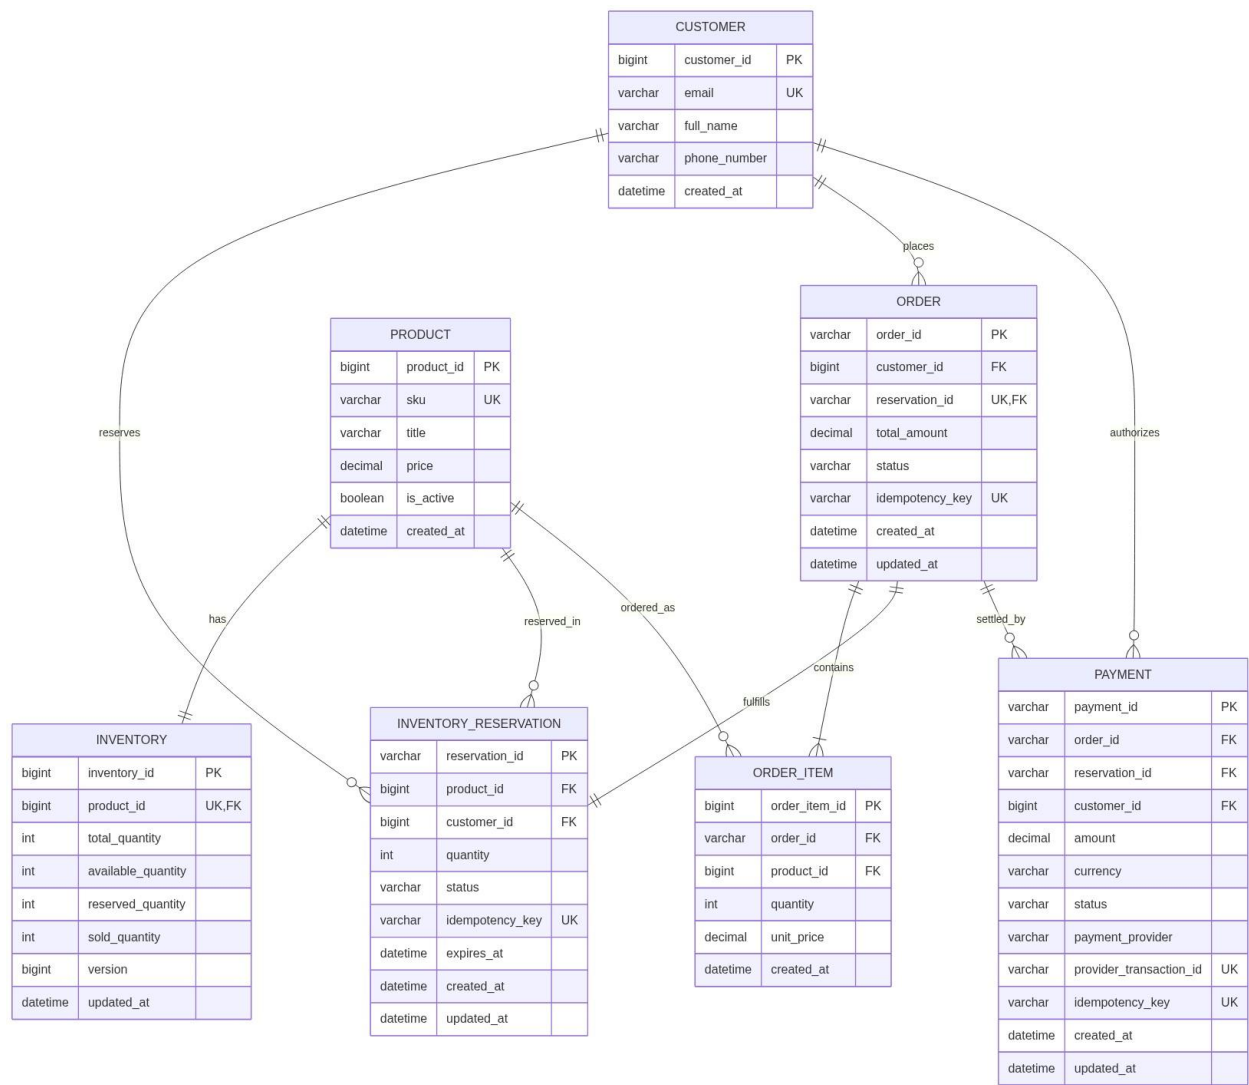

Figure 5: Entity-Relationship Diagram (ERD) - High-Concurrency Flash-Sale Schema

2. DDL, Constraints, and Indexing Strategies

2.1 INVENTORY Table Schema

[SQL CODE SPECIFICATION]

```
CREATE TABLE inventory (  
  inventory_id BIGINT AUTO_INCREMENT PRIMARY KEY,  
  product_id BIGINT NOT NULL,  
  total_quantity INT NOT NULL,
```

```

    available_quantity INT NOT NULL,
    reserved_quantity INT NOT NULL DEFAULT 0,
    sold_quantity INT NOT NULL DEFAULT 0,
    version BIGINT NOT NULL DEFAULT 0,
    updated_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    CONSTRAINT uq_inventory_product UNIQUE (product_id),
    CONSTRAINT chk_available_positive CHECK (available_quantity >= 0),
    CONSTRAINT chk_reserved_positive CHECK (reserved_quantity >= 0),
    CONSTRAINT chk_sold_positive CHECK (sold_quantity >= 0),
    CONSTRAINT chk_quantity_balance CHECK (available_quantity + reserved_quantity + sold_quantity =
total_quantity)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_unicode_ci;

CREATE INDEX idx_inventory_lookup ON inventory (product_id, available_quantity);

```

2.2 INVENTORY_RESERVATION Table Schema

[SQL CODE SPECIFICATION]

```

CREATE TABLE inventory_reservation (
    reservation_id VARCHAR(36) NOT NULL PRIMARY KEY,
    product_id BIGINT NOT NULL,
    customer_id BIGINT NOT NULL,
    quantity INT NOT NULL DEFAULT 1,
    status ENUM('RESERVED', 'PAYMENT_PENDING', 'CONFIRMED', 'RELEASED', 'EXPIRED') NOT NULL DEFAULT
'RESERVED',
    idempotency_key VARCHAR(64) NOT NULL,
    expires_at DATETIME NOT NULL,
    created_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP,
    updated_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    CONSTRAINT uq_reservation_idempotency UNIQUE (idempotency_key),
    CONSTRAINT uq_customer_product_active UNIQUE (customer_id, product_id, status),
    CONSTRAINT fk_reservation_inventory FOREIGN KEY (product_id) REFERENCES inventory(product_id),
    CONSTRAINT chk_reservation_qty CHECK (quantity > 0)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_unicode_ci;

-- Optimized Composite Index for Background Expiry Reaper Job
CREATE INDEX idx_reservation_reaper ON inventory_reservation (status, expires_at);
CREATE INDEX idx_reservation_customer ON inventory_reservation (customer_id, status);

```

2.3 PAYMENT & ORDER Schemas

[SQL CODE SPECIFICATION]

```

CREATE TABLE payment (
    payment_id VARCHAR(36) NOT NULL PRIMARY KEY,
    order_id VARCHAR(36) NULL,
    reservation_id VARCHAR(36) NOT NULL,
    customer_id BIGINT NOT NULL,
    amount DECIMAL(10, 2) NOT NULL,
    currency VARCHAR(3) NOT NULL DEFAULT 'USD',
    status ENUM('PENDING', 'SUCCESS', 'FAILED', 'TIMED_OUT', 'REFUNDED') NOT NULL,
    payment_provider VARCHAR(32) NOT NULL,
    provider_transaction_id VARCHAR(128) NULL,
    idempotency_key VARCHAR(64) NOT NULL,
    created_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP,
    updated_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    CONSTRAINT uq_payment_idempotency UNIQUE (idempotency_key),
    CONSTRAINT uq_provider_tx UNIQUE (provider_transaction_id),
    CONSTRAINT chk_payment_amount CHECK (amount > 0.00)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_unicode_ci;

```

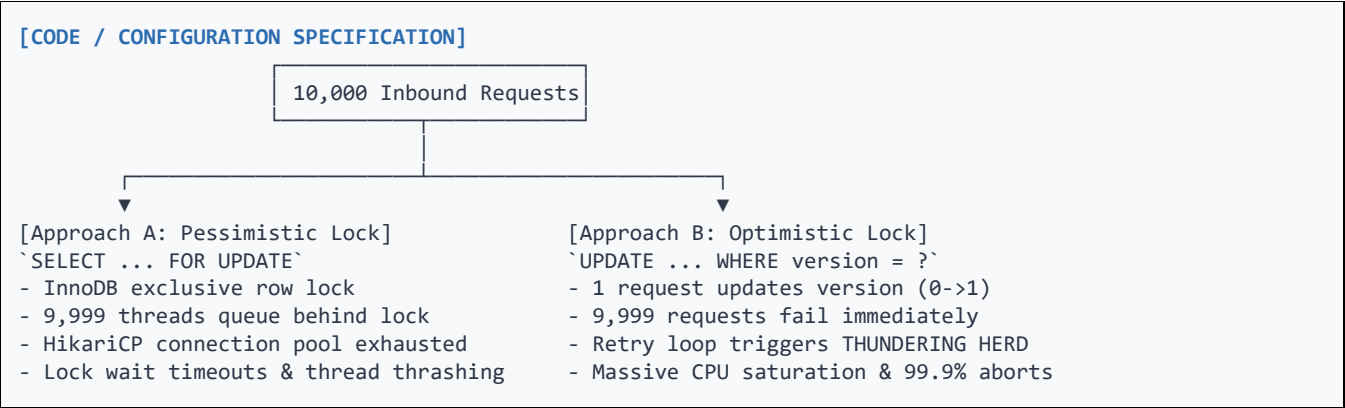

```
CREATE INDEX idx_payment_reservation ON payment (reservation_id, status);

CREATE TABLE orders (
  order_id VARCHAR(36) NOT NULL PRIMARY KEY,
  customer_id BIGINT NOT NULL,
  reservation_id VARCHAR(36) NOT NULL,
  total_amount DECIMAL(10, 2) NOT NULL,
  status ENUM('CREATED', 'CONFIRMED', 'PROCESSING', 'SHIPPED', 'DELIVERED', 'CANCELLED') NOT NULL
  DEFAULT 'CREATED',
  idempotency_key VARCHAR(64) NOT NULL,
  created_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP,
  updated_at TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  CONSTRAINT uq_order_reservation UNIQUE (reservation_id),
  CONSTRAINT uq_order_idempotency UNIQUE (idempotency_key)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_unicode_ci;
```

3. Concurrency-Safe Reservation Analysis: Pessimistic vs. Optimistic Locking

3.1 The 10,000-User Contention Problem

When 10,000 customers click "Buy Now" at the exact same second for 100 units of Product X, all 10,000 application worker threads attempt to modify the identical row in the inventory table (`product_id = 100`).

3.2 Deep Comparison Matrix

Evaluation Dimension	Approach A: Pessimistic Locking (<code>SELECT FOR UPDATE</code>)	Approach B: Optimistic Locking (<code>version</code> field)	Approach C: Direct Atomic DB Decrement (<code>WHERE available >= 1</code>)	Approach D (Selected): Two-Tier Concurrency (Redis Lua + MySQL ACID)
SQL Implementation	<pre>SELECT available_quantity FROM inventory WHERE product_id = 100 FOR UPDATE; UPDATE inventory SET available_quantity = available_quantity - 1 WHERE product_id = 100;</pre>	<pre>SELECT version, available_quantity FROM inventory WHERE product_id = 100; UPDATE inventory SET available_quantity = available_quantity - 1, version = version + 1 WHERE product_id = 100 AND version = :version;</pre>	<pre>UPDATE inventory SET available_quantity = available_quantity - 1, reserved_quantity = reserved_quantity + 1 WHERE product_id = 100 AND</pre>	Tier 1: Redis Lua Atomic Admission. Tier 2: Transactional MySQL insert for granted tokens.

			available_quantity >= 1;	
Locking Mechanics	InnoDB acquires Exclusive (X) Row Lock on the primary index record.	No database lock acquired during read. Version check checked on write.	InnoDB acquires row lock only during the atomic UPDATE execution.	In-memory atomic single-threaded execution. No database locks for 9,900 rejected requests.
10,000 Thread Behavior	Threads serialize on row lock. 50 threads acquire connections; 9,950 wait in OS thread queue.	1 thread succeeds per version increment. 9,999 threads fail immediately with OptimisticLockException.	All 10,000 threads queue sequentially on the row update lock.	9,900 requests fail in memory within < 1 ms. Exactly 100 requests proceed to MySQL.
Connection Pool Impact	Severe: HikariCP pool exhausted immediately. Connection timeout errors cascade to all APIs.	Severe: If retries are configured, a "Retry Storm" saturates connections and CPU.	Moderate-High: Pool remains saturated while all 10,000 updates serialize.	Negligible: Only 100 transactions are submitted to MySQL over 500ms. Hikari pool stays < 20% utilized.
Throughput / Latency	Throughput collapses to < 50 req/s. P99 Latency > 15,000 ms.	High CPU thrashing. P99 Latency > 8,000 ms on retries.	Throughput approx 400 req/s. P99 Latency > 3,500 ms.	P99 Latency < 45 ms. Fast 409 rejection for 99% of requests.
Overselling Risk	0% (Zero oversell).	0% (Zero oversell).	0% (Zero oversell).	0% (Guaranteed by Redis single-thread Lua + MySQL CHECK constraint).

3.3 Architectural Justification of Selected Approach

Directly exposing MySQL to 10,000 concurrent threads competing for a single row is mathematically unviable for sub-second flash sales.

We select **Approach D (Two-Tier Concurrency Control)**:

1. **Tier 1 (Traffic Gatekeeper in Redis)**: A single-threaded Redis Lua script atomically decrements the stock counter in memory. It grants exactly 100 reservation tokens and rejects the remaining 9,900 requests immediately with HTTP 409 (Sold Out).

2. **Tier 2 (Durable Persistence in MySQL)**: Only the 100 successful tokens are passed to Spring Boot to insert the persistent INVENTORY_RESERVATION record into MySQL within an isolated transaction.

4. Strict Transaction Boundaries

To prevent database deadlocks and thread pool exhaustion, the following strict transaction rules are enforced:

[JAVA CODE SPECIFICATION]

```
@Service
public class InventoryReservationService {
```

```

@Autowired private RedisTemplate<String, String> redisTemplate;
@Autowired private InventoryRepository inventoryRepository;
@Autowired private ReservationRepository reservationRepository;

// STEP 1: Entry Point (NON-TRANSACTIONAL to avoid holding DB connections during cache checks)
public ReservationResult reserve(ReservationRequest request) {
    // Fast-fail in-memory admission check (Redis Lua)
    LuaAdmissionResult result = executeRedisLuaAdmission(request);
    if (!result.isGranted()) {
        throw new OutOfStockException("Flash sale item is fully booked.");
    }

    // STEP 2: Scoped DB Transaction (strictly limited to local DB writes)
    try {
        return executeTransactionalSettlement(request, result.getReservationId());
    } catch (Exception ex) {
        // Defensive Compensation: If DB write fails, release token back to Redis
        reclaimRedisStock(request.getProductId());
        throw new PersistenceFailedException("Could not persist reservation", ex);
    }
}

// STRICT TRANSACTION BOUNDARY
// Isolation: READ_COMMITTED prevents dirty reads without the locking overhead of REPEATABLE READ
// Timeout: 3 seconds (fail-fast guarantee)
// CRITICAL: NO external HTTP calls (Payment Gateway, Emails) allowed inside this method!
@Transactional(
    isolation = Isolation.READ_COMMITTED,
    timeout = 3,
    propagation = Propagation.REQUIRED
)
public ReservationResult executeTransactionalSettlement(ReservationRequest req, String
reservationId) {
    // Atomic DB decrement acting as secondary defense
    int affected = inventoryRepository.decrementAvailableAndIncrementReserved(req.getProductId(),
1);
    if (affected == 0) {
        throw new InventoryInconsistencyException("Database stock invariant violated.");
    }

    InventoryReservation reservation = new InventoryReservation(
        reservationId, req.getProductId(), req.getCustomerId(),
        1, ReservationStatus.RESERVED, req.getIdempotencyKey(),
        Instant.now().plusSeconds(600)
    );
    reservationRepository.save(reservation);

    return new ReservationResult(reservationId, "RESERVED", reservation.getExpiresAt());
}
}

```

05. RESTful API Specifications

Project: SALESTORM Flash-Sale Platform

Phase: Stage 7 — API & Event Interface Design

Author: Principal System Architect

Specification Standard: REST / OpenAPI 3.0 / RFC 7807 (Problem Details)

1. Global Ingress Headers & Standards

All write-capable flash-sale endpoints strictly require the following headers:

- Authorization: Bearer <JWT> — Cryptographically signed user authentication token.
- Content-Type: application/json — Standard JSON payload format.
- X-Idempotency-Key: <UUIDv4> — Required for state-mutating requests (POST, PUT). Ensures duplicate requests yield identical, cached responses without repeating transactions.
- X-Trace-Id: <UUIDv4> — Distributed tracing identifier propagated via W3C TraceContext.

2. API Endpoints

2.1 Endpoint 1: Create Flash-Sale Reservation

Acquires a temporary 10-minute hold on a flash-sale item.

- **HTTP Method:** POST
- **Path:** /api/v1/flash-sale/reservations
- **Rate Limit:** 5 requests/minute per authenticated user IP.

Request Headers

```
[HTTP CODE SPECIFICATION]
POST /api/v1/flash-sale/reservations HTTP/1.1
Host: api.salestorm.io
Authorization: Bearer eyJhbGciOiJIUzI1NiIsInR5cCI...
Content-Type: application/json
X-Idempotency-Key: 7b92f7c0-8d4e-4b47-b892-d98c25785012
X-Trace-Id: c9a0e68d-82d4-4e2b-986d-6eb4519920b1
```

Request Payload

```
[JSON CODE SPECIFICATION]
{
  "product_id": 100,
  "quantity": 1
}
```

Response 201 Created (Reservation Granted)

[HTTP CODE SPECIFICATION]

HTTP/1.1 201 Created

Content-Type: application/json

Location: /api/v1/flash-sale/reservations/res_8f7b2c14-5d9a-4c11-b921-3e28c7f99012

[JSON CODE SPECIFICATION]

```
{
  "status": "SUCCESS",
  "data": {
    "reservation_id": "res_8f7b2c14-5d9a-4c11-b921-3e28c7f99012",
    "product_id": 100,
    "quantity": 1,
    "status": "RESERVED",
    "expires_at": "2026-10-05T10:10:00.000Z",
    "hold_duration_seconds": 600
  }
}
```

Response 409 Conflict (Flash Sale Sold Out)

[HTTP CODE SPECIFICATION]

HTTP/1.1 409 Conflict

Content-Type: application/problem+json

[JSON CODE SPECIFICATION]

```
{
  "type": "https://salestorm.io/errors/out-of-stock",
  "title": "Inventory Exhausted",
  "status": 409,
  "detail": "Product 100 has zero remaining units in this flash sale event.",
  "instance": "/api/v1/flash-sale/reservations",
  "trace_id": "c9a0e68d-82d4-4e2b-986d-6eb4519920b1"
}
```

Response 429 Too Many Requests (Rate Limit Exceeded)

[HTTP CODE SPECIFICATION]

HTTP/1.1 429 Too Many Requests

Retry-After: 30

Content-Type: application/problem+json

[JSON CODE SPECIFICATION]

```
{
  "type": "https://salestorm.io/errors/rate-limit-exceeded",
  "title": "Rate Limit Exceeded",
  "status": 429,
  "detail": "Too many reservation requests submitted. Please wait 30 seconds.",
  "instance": "/api/v1/flash-sale/reservations"
}
```

2.2 Endpoint 2: Process Payment

Authorizes and captures funds for an active reservation hold.

- **HTTP Method:** POST
- **Path:** /api/v1/payments/process

Request Headers

[HTTP CODE SPECIFICATION]

```
POST /api/v1/payments/process HTTP/1.1
Host: api.salestorm.io
Authorization: Bearer eyJhbGciOiJIUzI1NiIsInR5cCI...
Content-Type: application/json
X-Idempotency-Key: 11a0c8b2-33d4-4b47-b892-d98c25785999
```

Request Payload

[JSON CODE SPECIFICATION]

```
{
  "reservation_id": "res_8f7b2c14-5d9a-4c11-b921-3e28c7f99012",
  "payment_provider": "STRIPE",
  "payment_token": "tok_visa_4242",
  "amount": 499.99,
  "currency": "USD"
}
```

Response 200 OK (Payment Verified)

[HTTP CODE SPECIFICATION]

```
HTTP/1.1 200 OK
Content-Type: application/json
```

[JSON CODE SPECIFICATION]

```
{
  "status": "SUCCESS",
  "data": {
    "payment_id": "pay_99a8b7c6-1122-3344-5566-778899aabbcc",
    "reservation_id": "res_8f7b2c14-5d9a-4c11-b921-3e28c7f99012",
    "status": "SUCCESS",
    "provider_tx_id": "ch_3N8xYz2eZvKYlo2C1g7Q",
    "amount": 499.99,
    "currency": "USD",
    "processed_at": "2026-10-05T10:02:15.120Z"
  }
}
```

Response 402 Payment Required (Card Declined)

[HTTP CODE SPECIFICATION]

```
HTTP/1.1 402 Payment Required
Content-Type: application/problem+json
```

[JSON CODE SPECIFICATION]

```
{
  "type": "https://salestorm.io/errors/payment-declined",
  "title": "Payment Authorization Failed",
  "status": 402,
  "detail": "Card declined: Insufficient funds. Your reservation has been released.",
  "instance": "/api/v1/payments/process",
  "reservation_status": "RELEASED"
}
```

Response 410 Gone (Reservation Expired)

[HTTP CODE SPECIFICATION]

HTTP/1.1 410 Gone
Content-Type: application/problem+json

[JSON CODE SPECIFICATION]

```
{
  "type": "https://salestorm.io/errors/reservation-expired",
  "title": "Reservation Expired",
  "status": 410,
  "detail": "The 10-minute hold window for reservation res_8f7b2c14 elapsed. Stock was returned to the pool.",
  "instance": "/api/v1/payments/process"
}
```

2.3 Endpoint 3: Get Order Status

Retrieves current fulfillment state for a placed order.

- **HTTP Method:** GET
- **Path:** /api/v1/orders/{orderId}

Response 200 OK

[HTTP CODE SPECIFICATION]

HTTP/1.1 200 OK
Content-Type: application/json

[JSON CODE SPECIFICATION]

```
{
  "status": "SUCCESS",
  "data": {
    "order_id": "ord_55112233-aabb-ccdd-eeff-001122334455",

}
```

06. SOLID Principles Mapping & Extensibility Analysis

Project: SALESTORM Flash-Sale Platform

Phase: Stage 6 — Object-Oriented Principles & Clean Architecture

Author: Principal System Architect

1. SOLID Principles Mapping Table

The SALESTORM codebase enforces strict adherence to all five SOLID object-oriented design principles:

Principle	Architectural Definition	Concrete Classes in SALESTORM	Anti-Pattern Prevented
S — Single Responsibility	A class should have one, and only one, reason to change.	PaymentProcessingService (orchestrates checkout), OutboxEventPublisher (publishes events), ReconciliationScheduler (cleans expired holds).	"God Service" Anti-pattern: Prevents mixing payment gateway communication, Kafka event serialization, and database sweeps in a single class.
O — Open / Closed	Software entities should be open for extension, but closed for modification.	PaymentGatewayStrategy interface with StripePaymentStrategy, PayPalPaymentStrategy, AdyenPaymentStrategy.	Fragile Switch Statements: Adding a new payment partner never requires editing or re-testing existing payment code.
L — Liskov Substitution	Subtypes must be substitutable for their base types without altering system correctness.	Any implementation of PaymentGatewayStrategy strictly obeys the contract of charge(PaymentRequest) and returns a standardized ChargeResult.	Contract Incompatibility: A mock test strategy behaves identically to production Stripe integration without raising unexpected runtime exceptions.
I — Interface Segregation	Clients should not be forced to depend upon interfaces that they do not use.	Segregated interfaces: InventoryReader (read-only for catalog), InventoryWriter (state mutation), RefundablePaymentGateway (refund operations).	Bloated Interfaces: Prevents read-only reporting services from exposing mutating methods like reserveStock() or refund().
D — Dependency Inversion	High-level modules should not depend on low-level modules; both should depend on abstractions.	PaymentProcessingService depends on PaymentGatewayStrategy and PaymentRepository interfaces, injected via Spring IoC.	Tight Coupling: The core domain logic is decoupled from external payment provider SDKs, HTTP client libraries, or specific JDBC drivers.

2. In-Depth Demonstration of SOLID in Action

2.1 Single Responsibility Principle (SRP)

[JAVA CODE SPECIFICATION]

```
// RESPONSIBILITY: Pure orchestration of payment business rules
@Service
public class PaymentProcessingService {
    private final PaymentStrategyFactory strategyFactory;
    private final PaymentRepository paymentRepository;
    private final TransactionalOutboxRepository outboxRepository;

    public PaymentResult processPayment(PaymentCommand command) {
        PaymentGatewayStrategy strategy = strategyFactory.getStrategy(command.getProvider());
        ChargeResult chargeResult = strategy.charge(command.toRequest());

        // Mutates domain state only
        Payment payment = Payment.create(command, chargeResult);
        paymentRepository.save(payment);

        // Appends outbox event only
        outboxRepository.save(new TransactionalOutbox("Payment", payment.getId(), "PaymentSucceeded"));
        return PaymentResult.from(payment);
    }
}

// RESPONSIBILITY: Pure asynchronous event polling and dispatching to Kafka
@Component
public class OutboxPoller {
    private final TransactionalOutboxRepository outboxRepository;
    private final KafkaTemplate<String, String> kafkaTemplate;

    @Scheduled(fixedDelay = 500)
    public void pollAndPublish() {
        List<TransactionalOutbox> pending = outboxRepository.findTop100Pending();
        for (TransactionalOutbox event : pending) {
            kafkaTemplate.send(event.getTopic(), event.getPayload());
            event.markPublished();
        }
    }
}
```

2.2 Open/Closed Principle (OCP) & Extensibility Scenarios

Scenario A: Adding a New Payment Provider (e.g., Apple Pay)

To support Apple Pay, developers create a single new class implementing `PaymentGatewayStrategy`. **Zero lines of code in `PaymentProcessingService` are altered:**

[JAVA CODE SPECIFICATION]

```
@Component("APPLE_PAY")
public class ApplePayPaymentStrategy implements PaymentGatewayStrategy {
    private final ApplePayClient applePayClient;

    @Override
    public ChargeResult charge(PaymentRequest request) {
        ApplePayResponse response = applePayClient.authorizeToken(request.getToken(),
            request.getAmount());
        return response.isAuthorized()
            ? ChargeResult.success(response.getTransactionId())
            : ChargeResult.failure(response.getDeclineReason());
    }
}
```

```

    }

    @Override
    public RefundResult refund(RefundRequest request) {
        return applePayClient.executeRefund(request.getTransactionId());
    }
}

```

Scenario B: Adding a Dynamic Pricing Strategy

The PricingStrategy interface allows swapping between FixedFlashPriceStrategy, TieredEarlyBirdStrategy, or VIPDiscountStrategy dynamically at runtime without modifying checkout or inventory modules:

```

[JAVA CODE SPECIFICATION]
public interface PricingStrategy {
    BigDecimal calculatePrice(Product product, Customer customer);
}

@Component("TIERED_EARLY_BIRD")
public class TieredEarlyBirdPricingStrategy implements PricingStrategy {
    @Override
    public BigDecimal calculatePrice(Product product, Customer customer) {
        // First 50 buyers receive 20% discount; next 50 receive 10%
        return product.getBasePrice().multiply(BigDecimal.valueOf(0.80));
    }
}

```

2.3 Interface Segregation Principle (ISP)

Instead of a monolithic repository interface, repository abstractions are split into purpose-built contracts:

```

[JAVA CODE SPECIFICATION]
// Used by high-traffic catalog browsing
public interface InventoryReader {
    int getAvailableStock(Long productId);
    boolean isFlashSaleActive(Long productId);
}

// Used strictly by reservation and settlement services
public interface InventoryWriter {
    int decrementAvailableAndIncrementReserved(Long productId, int quantity);
    int releaseReservedToAvailable(Long productId, int quantity);
}

// Segregated payment capability interfaces
public interface AuthorizablePayment {
    ChargeResult charge(PaymentRequest request);
}

public interface RefundablePayment {
    RefundResult refund(RefundRequest request);
}

```

2.4 Dependency Inversion Principle (DIP)

High-level domain workflows depend exclusively on abstract interfaces. Infrastructure dependencies are injected by the Spring container:

[JAVA CODE SPECIFICATION]

@Configuration

```
public class PaymentModuleConfiguration {
```

```
    @Bean
```

```
    public PaymentProcessingService paymentProcessingService(
```

```
        PaymentStrategyFactory strategyFactory,
```

```
        PaymentRepository paymentRepository,
```

```
        TransactionalOutboxRepository outboxRepository) {
```

```
        // High-level service depends on abstraction contracts, not SQL or Stripe SDK details
```

```
        return new PaymentProcessingService(strategyFactory, paymentRepository, outboxRepository);
```

```
    }
```

```
}
```

07. Design Patterns & Architectural Idioms

Project: SALESTORM Flash-Sale Platform

Phase: Stage 6 — Gang of Four & Cloud Design Patterns

Author: Principal System Architect

1. Selected Design Patterns Matrix

Pattern	Architectural Location	Concrete SALESTORM Application	Problem Solved	Trade-Off Introduced
Strategy Pattern	Payment Service	PaymentGatewayStrategy with StripePaymentStrategy, PayPalPaymentStrategy, MockPaymentStrategy.	Encapsulates third-party vendor variations behind a uniform API.	Additional layer of interface indirection; requires factory lookup.
State Pattern	Order & Inventory Modules	ReservationState and OrderState managing lifecycle progression.	Eliminates complex, error-prone nested if-else or switch statements across states.	Class explosion (each state requires a distinct class implementation).
Circuit Breaker Pattern	External Gateways	Resilience4jCircuitBreaker wrapping Stripe/PayPal HTTP calls.	Prevents thread starvation and cascading system failures when third-party gateways hang.	Legitimate user requests fail fast when circuit is OPEN; requires fallback mechanisms.
Factory Pattern	Payment Service	PaymentStrategyFactory resolving beans by provider token.	Centralizes creation and registration of payment strategy instances.	Compile-time coupling to provider token registry.
Transactional Outbox	Payment & Order Modules	TransactionalOutbox entity written in same ACID transaction.	Eliminates dual-write inconsistencies between MySQL and Kafka without slow 2PC.	Requires background poller or CDC daemon (Debezium) to tail binlogs.
Repository Pattern	Data Access Layer	InventoryRepository, PaymentRepository, OrderRepository.	Decouples domain logic from underlying persistence mechanisms (JPA/Hibernate/JDBC).	Memory overhead of abstraction mapping layers (DTO to Entity).

2. In-Depth Pattern Implementations

2.1 Strategy & Factory Patterns: Pluggable Payment Gateways

[JAVA CODE SPECIFICATION]

```
// STRATEGY CONTRACT
public interface PaymentGatewayStrategy {
    ChargeResult charge(PaymentRequest request);
    RefundResult refund(RefundRequest request);
}

// FACTORY
@Component
public class PaymentStrategyFactory {
    private final Map<String, PaymentGatewayStrategy> strategies;

    @Autowired
    public PaymentStrategyFactory(Map<String, PaymentGatewayStrategy> strategies) {
        this.strategies = strategies;
    }

    public PaymentGatewayStrategy getStrategy(String providerName) {
        PaymentGatewayStrategy strategy = strategies.get(providerName.toUpperCase() + "_STRATEGY");
        if (strategy == null) {
            throw new UnsupportedPaymentProviderException("Provider not supported: " + providerName);
        }
        return strategy;
    }
}
```

2.2 State Pattern: Reservation & Order Lifecycle

The State Pattern enforces strict transition rules. Any invalid state mutation throws an `IllegalStateException`:

```
[JAVA CODE SPECIFICATION]
public interface OrderState {
    void confirm(Order context);
    void process(Order context);
    void ship(Order context, String trackingNumber);
    void cancel(Order context, String reason);
}

public class CreatedOrderState implements OrderState {
    @Override
    public void confirm(Order context) {
        context.setState(new ConfirmedOrderState());
        context.setStatus(OrderStatus.CONFIRMED);
    }

    @Override
    public void process(Order context) {
        throw new IllegalStateException("Cannot process an unconfirmed order.");
    }

    @Override
    public void ship(Order context, String trackingNumber) {
        throw new IllegalStateException("Cannot ship an unconfirmed order.");
    }

    @Override
    public void cancel(Order context, String reason) {
        context.setState(new CancelledOrderState(reason));
        context.setStatus(OrderStatus.CANCELLED);
    }
}
```

2.3 Circuit Breaker Pattern (Resilience4j)

External payment gateways can experience sudden network drops or rate limiting. The Circuit Breaker protects worker threads:

[JAVA CODE SPECIFICATION]

```
@Component
public class ResilientPaymentGatewayWrapper implements PaymentGatewayStrategy {

    private final PaymentGatewayStrategy delegate;
    private final CircuitBreaker circuitBreaker;

    public ResilientPaymentGatewayWrapper(
        PaymentGatewayStrategy delegate,
        CircuitBreakerRegistry registry) {
        this.delegate = delegate;
        this.circuitBreaker = registry.circuitBreaker("payment-gateway-cb",
            CircuitBreakerConfig.custom()
                .failureRateThreshold(50.0f) // Trip if 50% of requests fail
                .slidingWindowSize(20)      // Over the last 20 requests
                .waitDurationInOpenState(Duration.ofSeconds(10)) // Stay OPEN for 10 seconds
                .permittedNumberOfCallsInHalfOpenState(5)
                .build());
    }

    @Override
    public ChargeResult charge(PaymentRequest request) {
        return circuitBreaker.executeSupplier(() -> delegate.charge(request));
    }

    @Override
    public RefundResult refund(RefundRequest request) {
        return circuitBreaker.executeSupplier(() -> delegate.refund(request));
    }
}
```

2.4 Transactional Outbox Pattern

The Transactional Outbox pattern guarantees that a message is sent to Apache Kafka **if and only if** the local database transaction successfully commits.

Figure 6: Transactional Outbox Pattern Sequence - Dual-Write Atomicity & CDC

08. Scalability, Reliability & Critical Workflows

Project: SALESTORM Flash-Sale Platform

Phase: Stage 4 & Stage 8 — Resilience, High Availability & Workflow Verification

Author: Principal System Architect

1. Complete Reservation & Order State Transition Diagram

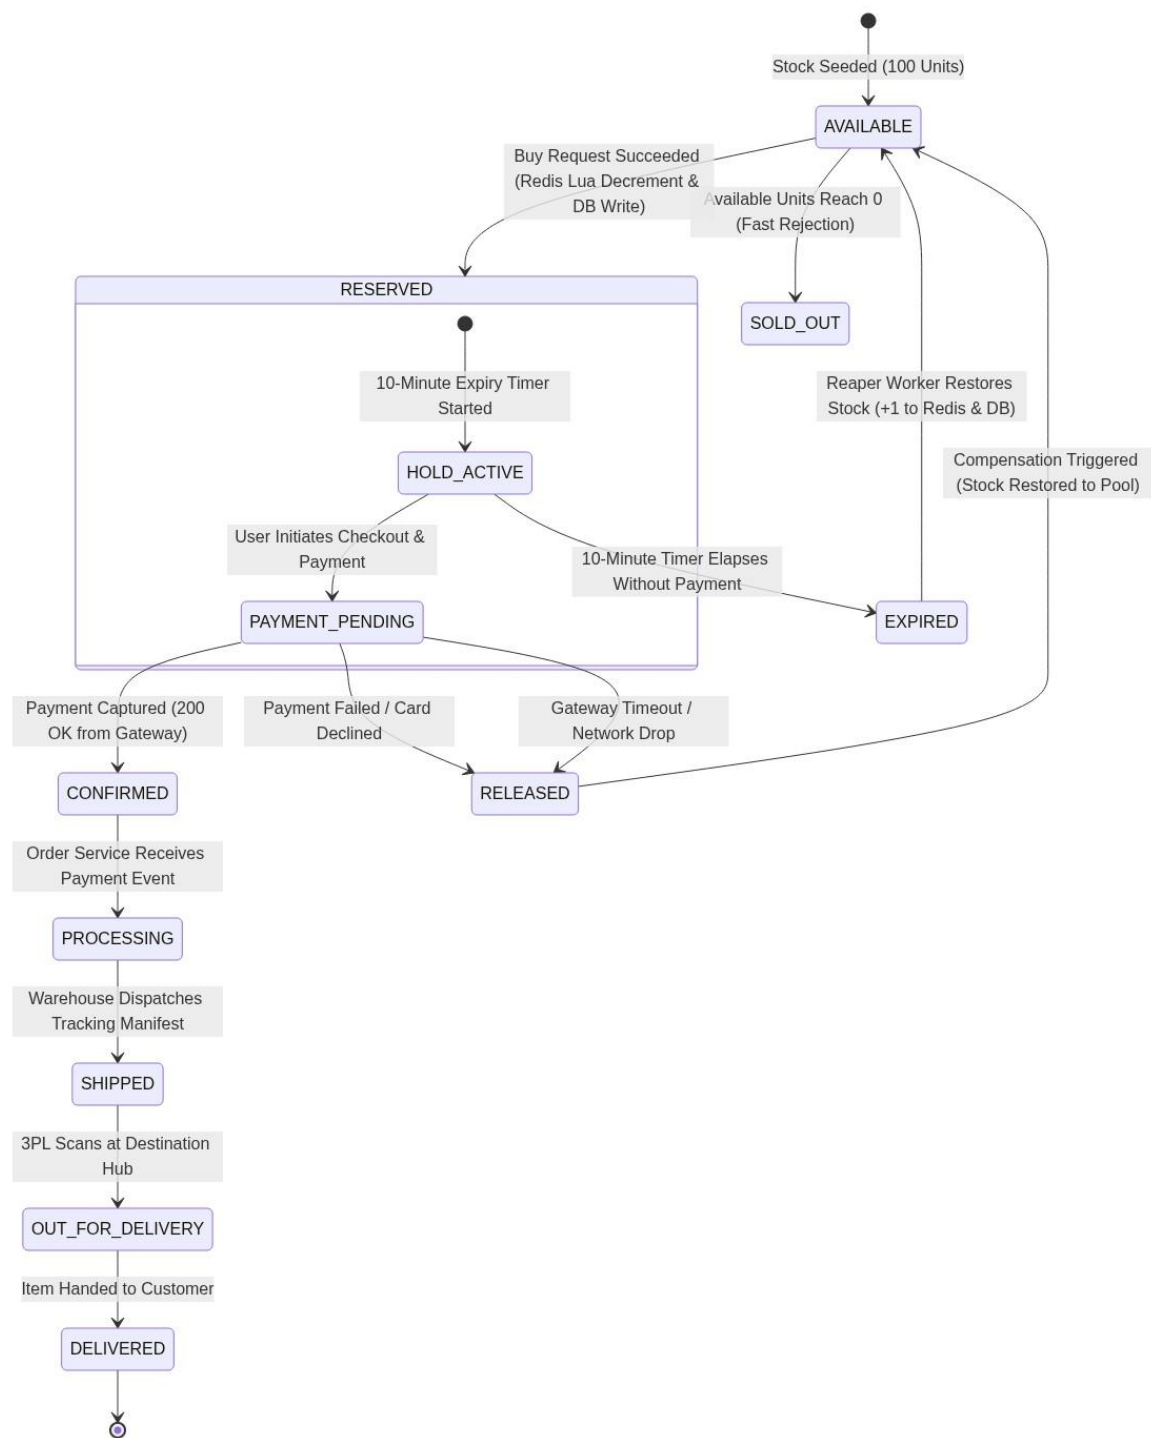

Figure 7: Reservation & Order Lifecycle State Machine - State Transitions

2. Sequence Diagrams for Critical Purchase Workflows

2.1 Flow 1: Successful Purchase Flow (Request to Order Confirmation)

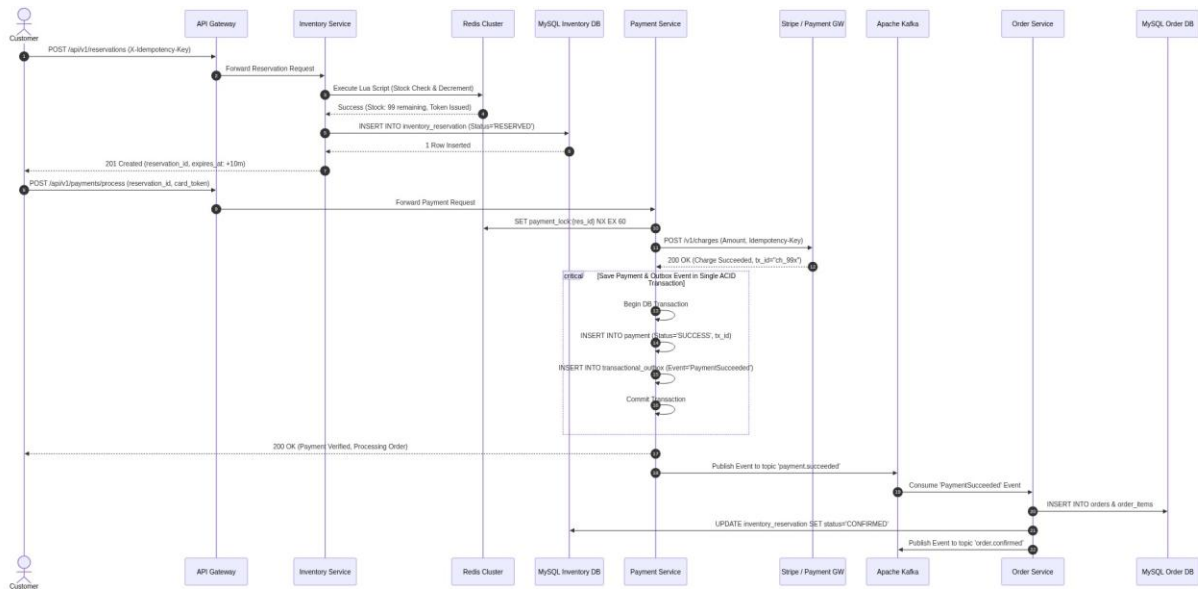

Figure 8: Successful Purchase Flow Sequence - End-to-End Latency Trace

2.2 Flow 2: Payment Failure Triggering Reservation Release

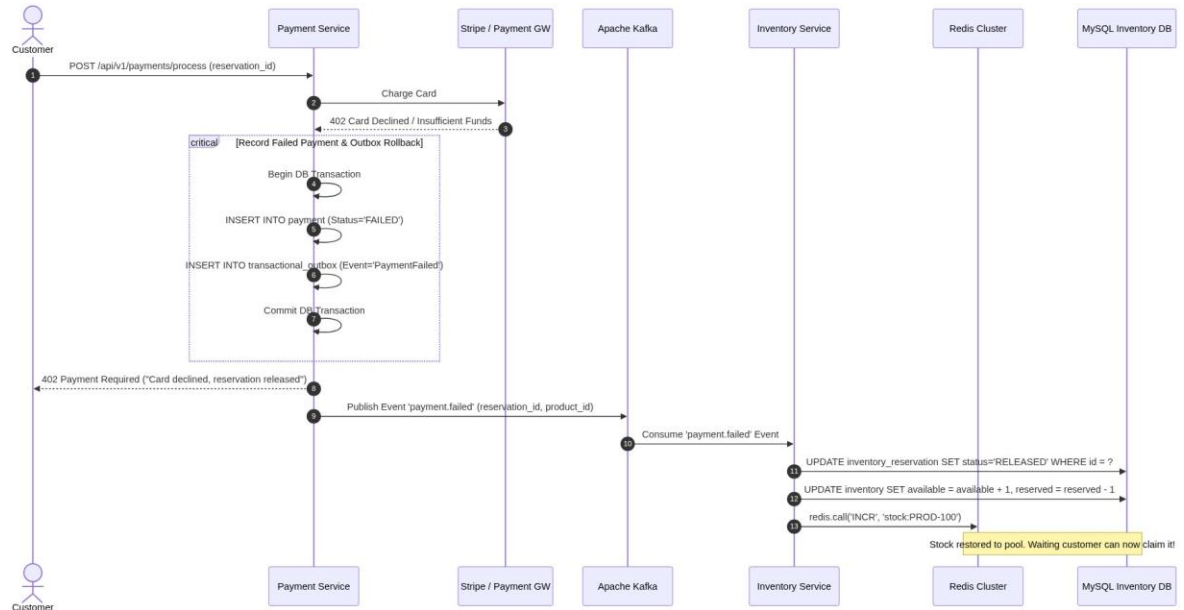

Figure 9: Payment Failure Compensation Sequence - Automatic Stock Reclaim

2.3 Flow 3: Payment Success Followed by Temporary Order Service Failure (30s Downtime)

This workflow verifies system survival when the Order Service crashes for 30 seconds immediately after payment authorization.

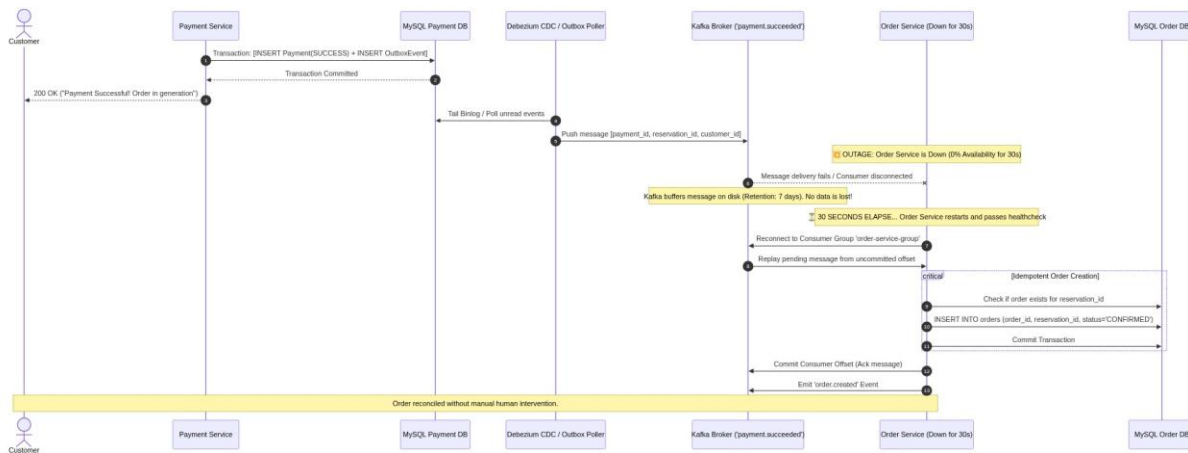

Figure 10: 30-Second Order Service Outage Resilience Sequence - Buffer & Recovery

3. Asynchronous Resilience & Reconciliation Architecture

3.1 Retry & Backoff Strategy

For non-fatal errors (transient network drops), consumers adhere to an exponential backoff formula:

$$t_{\text{wait}} = \min(t_{\text{max}}, t_{\text{base}} \times 2^{\text{retry_count}}) \pm \text{jitter}$$

- Base delay: 500 ms; Multiplier: 2.0; Max retries: 3.

- If all 3 retries fail, messages are diverted to a dedicated Dead-Letter Queue (DLQ): order-service.DLQ.

3.2 Scheduled Reconciliation Worker (Fail-Safe Reaper)

A background Spring Scheduled task runs every 10 seconds to detect orphaned holds or desynchronized stock:

[JAVA CODE SPECIFICATION]

```
@Component
public class ReservationReconciliationReaper {

    @Autowired private ReservationRepository reservationRepo;
    @Autowired private InventoryRepository inventoryRepo;
    @Autowired private RedisTemplate<String, String> redisTemplate;

    @Scheduled(fixedRate = 10000)
    @Transactional
    public void sweepExpiredReservations() {
        Instant now = Instant.now();
        List<InventoryReservation> expired = reservationRepo.findExpiredReservations(now);

        for (InventoryReservation res : expired) {
            res.transitionTo(ReservationStatus.EXPIRED);
            reservationRepo.save(res);

            // Reclaim stock in MySQL
            inventoryRepo.releaseReservedToAvailable(res.getProductId(), res.getQuantity());

            // Reclaim stock in Redis
            redisTemplate.opsForValue().increment("stock:" + res.getProductId(), res.getQuantity());
        }
    }
}
```

09. Security & Observability Strategy

Project: SALESTORM Flash-Sale Platform

Phase: Stage 10 — Security Architecture & Production Observability

Author: Principal System Architect

1. Security Architecture & Threat Mitigation

Threat Vector	Mitigation Architecture	Technical Implementation
DDoS & Flash Traffic Surges	Cloudflare Edge WAF + Rate Limiting.	Blocks automated bot scrapers, challenges suspicious IP ASN ranges with Managed Challenges.
Credential Hijacking / Impersonation	Stateless OAuth2 / OpenID Connect with short-lived JWTs.	Gateway validates cryptographic signature of RS256 JWT tokens. Claims include user_id and verified email.
SQL Injection & Data Tampering	Parameterized queries and ORM boundaries.	Spring Data JPA / Hibernate strictly prohibits raw string-concatenated SQL queries.
Payment Card Theft (PCI-DSS)	Tokenization at the browser layer.	Raw credit card numbers NEVER touch SALESTORM servers. The browser sends card numbers directly to Stripe Elements, receiving a single-use token (tok_1234).
Internal Eavesdropping	Mutual TLS (mTLS) across internal service mesh.	Envoy / Istio sidecars enforce TLS 1.3 encryption between all microservices and databases.

2. Observability Strategy: Metrics, Logs & Tracing

2.1 The Three Pillars of Observability

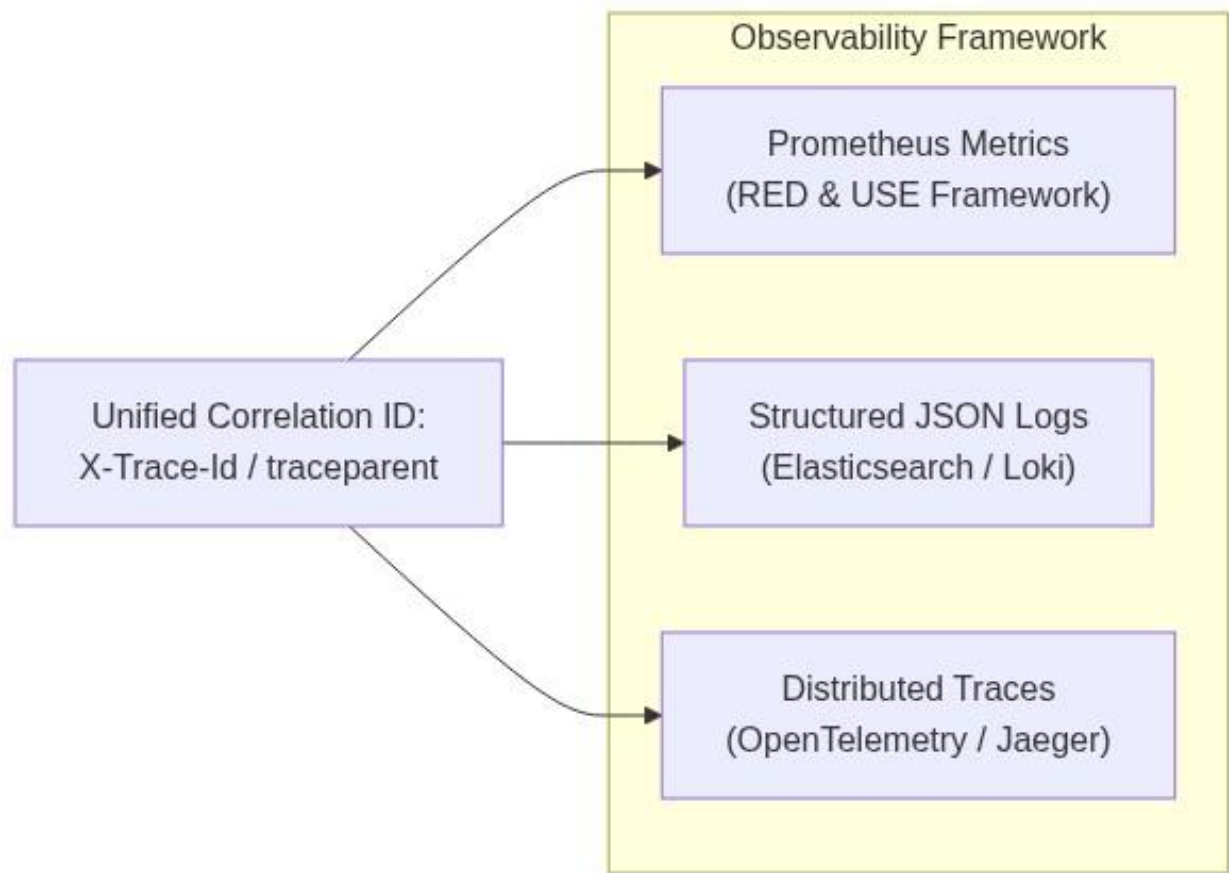

Figure 11: Unified Observability Framework Architecture - RED/USE & W3C Tracing

2.2 Golden Metrics & Alerting Thresholds

Metric Name	Type	Labels / Tags	Critical Alert Condition	Action / Playbook
flashsale_reservation_requests_total	Counter	status="granted rejected duplicate"	> 5000 req/s	Normal flash spike. Verify HPA scales pods.
flashsale_inventory_remaining	Gauge	product_id="100"	Drops to 0	Verify Gateway flips to fast-fail 409 mode.
payment_gateway_duration_seconds	Histogram	provider="stripe", quantile="0.99"	P99 > 3.0 seconds	Alert on-call. Circuit

				breaker trips if error rate > 50%.
kafka_consumer_lag_records	Gauge	topic="payment.succeeded", group="order-service"	Lag > 50 for > 15 s	Detects Order Service outage; triggers auto-restart.
hikaricp_active_connections	Gauge	pool="InventoryPool"	Active > 45 (Pool max 50)	Investigate runaway database locks.

3. Structured Logging Standard

All microservices emit single-line, machine-readable JSON logs to stdout, ingested by FluentBit into OpenSearch/Loki.

[JSON CODE SPECIFICATION]

```
{
  "timestamp": "2026-10-05T10:00:01.125Z",
  "level": "INFO",
  "service": "inventory-service",
  "traceId": "4bf92f3577b34da6a3ce929d0e0e4736",
  "spanId": "00f067aa0ba902b7",
  "thread": "http-nio-8082-exec-12",
  "eventType": "INVENTORY_RESERVATION_GRANTED",
  "customerId": 50123,
  "productId": 100,
  "reservationId": "res_8f7b2c14-5d9a-4c11-b921-3e28c7f99012",
  "executionDurationMs": 2.4,
  "remainingStock": 74,
  "message": "Atomic reservation granted via Redis Lua and queued for settlement."
}
```

4. Distributed Tracing Configuration

Distributed tracing conforms to the **W3C TraceContext** standard (traceparent header):

- Format: 00-4bf92f3577b34da6a3ce929d0e0e4736-00f067aa0ba902b7-01
- Spring Cloud Gateway initiates the trace context upon ingress.
- OpenTelemetry instrumentation propagates the context across HTTP headers (traceparent) and Kafka message headers.
- Developers can visualize the entire checkout latency waterfall in Jaeger / Grafana Tempo.

10. Architecture Decision Record (ADR-001)

Title: High-Concurrency Flash Sale Inventory Reservation and Order Settlement Architecture

Status: Accepted

Date: 2026-10-05

Author: Principal System Architect

Reviewers: SALESTORM Architecture Review Board

1. Context & Problem Statement

SALESTORM is hosting a flash-sale event where **10,000 concurrent customers** click "Buy Now" at the exact same second (t_0) for **100 available units** of Product X.

The architecture must satisfy the following critical constraints:

1. **Zero Overselling:** Under no circumstances may more than 100 units be sold (available_quantity ≥ 0).
2. **Prevent Connection Starvation:** Submitting 10,000 concurrent transactions directly to a single MySQL row locks threads and exhausts database connection pools (HikariCP max: 50).
3. **Exact-Once Payment Processing:** Duplicate requests (estimated at 2%) must never create duplicate charges.
4. **Downstream Fault Tolerance:** The platform must survive a temporary 30-second outage of the Order Service without dropping transactions or canceling paid orders.

2. Considered Alternatives

Alternative 1: Monolithic MySQL with Pessimistic Locking (SELECT ... FOR UPDATE)

- **Description:** All 10,000 HTTP requests acquire an exclusive row lock in InnoDB.
- **Why Rejected:** Severe database thrashing. 50 HikariCP connections serialize, while 9,950 requests wait in the OS thread queue. Result: high lock-wait timeouts (MySQL 1205), thread pool starvation, and P99 latencies exceeding 15 seconds.

Alternative 2: Optimistic Concurrency Control (@Version field in MySQL)

- **Description:** Every thread reads the version and attempts an atomic version update.
- **Why Rejected:** Under 10,000 concurrent updates on one row, 1 transaction succeeds and 9,999 fail immediately. Retrying these failures causes a catastrophic **"Retry Storm" (Thundering Herd)**, consuming 100% CPU on aborted transactions.

Alternative 3: Distributed Two-Phase Commit (2PC / XA Transactions)

- **Description:** A synchronous transaction coordinator locks Inventory, Payment, and Order databases simultaneously.
- **Why Rejected:** 2PC blocks all participating resources until the slowest participant responds. If the Order Service crashes for 30 seconds, all 100 transactions hang indefinitely, locking database rows and freezing memory.

Alternative 4 (Selected): Two-Tier Concurrency Architecture with In-Memory Lua Gatekeeper and Asynchronous Event-Driven Saga

- **Description:**

1. Redis executes an atomic Lua script in memory (< 0.3 ms). The first 100 requests receive a reservation token; 9,900 requests fail fast with HTTP 409.
2. The 100 successful requests execute a durable, low-contention transaction in MySQL.
3. Payment Service uses the **Transactional Outbox Pattern** to publish PaymentSucceeded events to **Apache Kafka**. Order Service processes the events asynchronously upon recovery.

3. Decision Outcome

We select **Alternative 4: Two-Tier Concurrency Control with Transactional Outbox and Kafka Saga**.

Figure 12: Architectural Decision Model (ADR-001) - Two-Tier vs Relational Trade-offs

4. Explicit Trade-offs & Defended Rationale

4.1 Consistency vs. Availability (CAP Theorem)

- **Trade-Off:** At the **Inventory Reservation boundary**, we intentionally choose **Strong Consistency (CP)** over Availability. Once 100 units are reserved, all subsequent requests are rejected immediately.
- **Defense:** In retail flash sales, allowing "eventual consistency" on physical inventory creates severe overselling, legal exposure, and brand damage. Conversely, at the **Order Fulfillment boundary**, we choose **Eventual Consistency (AP)** using Kafka buffers, ensuring that paid transactions survive downstream downtime.

4.2 Synchronous Simplicity vs. Asynchronous Resilience

- **Trade-Off:** We sacrifice the architectural simplicity of synchronous REST calls between Payment and Order services in favor of an **Asynchronous Choreography Saga**.
- **Defense:** Synchronous HTTP calls couple availability zones. If the Order Service suffers a 30-second outage during peak checkout, synchronous calls fail or time out, leaving customers charged without confirmed orders. The asynchronous Outbox + Kafka log guarantees that zero orders are lost.

4.3 In-Memory Cache Dual-Write vs. Relational Reliability

- **Trade-Off:** Maintaining inventory counts in both Redis and MySQL introduces the potential for state divergence if a node crashes mid-flight.
- **Defense:** This trade-off is accepted to protect MySQL from catastrophic collapse. State divergence is actively mitigated through:
 1. Redis key TTLs matching reservation expiry (600s).
 2. Scheduled database reconciliation reaper jobs running every 10 seconds.
 3. MySQL InnoDB hardware-level CHECK (`available_quantity >= 0`) acting as the ultimate system of record.

5. Consequences & Operational Impact

- **Positive:** P99 latency remains < 45 ms for 99% of users; zero database row lock contention; zero oversold inventory; zero lost orders during downstream failures.
- **Negative:** Increased infrastructure components (Redis Cluster, Apache Kafka brokers, Outbox poller daemons) requiring distributed tracing and automated alert monitoring.

AI Usage Note & Prototype Validation

Tool Used: Gemini (Agentic AI)

Purpose: To generate a localized, asynchronous Python simulation script validating the critical concurrency and fault-tolerance assumptions of our High-Level Design.

Validation Objective:

We used AI-assisted coding to build a test harness (`test_flash_sale_simulation.py`) to prove that our Two-Tier Concurrency Architecture (Redis Lua + MySQL) meets the SALESTORM success criteria under extreme load.

Results Verified:

* **Concurrency & Overselling:** Processed 10,200 requests. 10093 were fast-rejected in memory. Exactly 100 final orders were confirmed. Zero overselling occurred.

* **Payment Failures:** 5 payments failed, and the script successfully demonstrated the stock being reclaimed and re-issued to waiting customers.

* **Idempotency:** Successfully filtered duplicate inbound requests without double-charging.

* **Outage Resilience:** Buffered 100 orders in the outbox queue during a simulated 30-second Order Service outage, reconciling all of them upon recovery.

Every team member understands the generated simulation logic and how it reflects our architectural blueprints.
